

Aeris Final Ideas and Features

Ideas are broad solution directions. Features are specific functions available in the application. The items are ranked from most important and useful to supporting functions.

Aeris is an all-in-one travel planning and booking platform with optional AI assistance. Travellers can manually browse, filter, compare and select available travel options. They can also use Aeris AI to receive personalised recommendations, build an itinerary, coordinate a group and respond when plans change. The traveller always controls the final selection, booking, payment and itinerary update.

Ideas

1. All in One Travel Planning and Booking Platform

Description: A single application where travellers can browse available flights, accommodation, transport, restaurants, attractions and activities; compare options; build an itinerary; complete bookings; manage costs; and store the confirmed trip. Manual search remains available at every stage, so users do not have to depend on AI recommendations.

Example: A traveller searches for flights and hotels using dates, destination, price and rating filters. They compare the results, choose their preferred options, complete the approved bookings and see everything organised in one trip dashboard.

2. Personalised AI Travel Companion

Description: An optional AI assistant that uses the traveller's answers, saved preferences, budget, trip information, current location and permitted calendar data to make relevant suggestions. It can search available options, explain comparisons, create a draft itinerary and help the traveller make decisions, while still allowing the traveller to browse and edit everything manually.

Example: A solo traveller answers personalisation questions and connects Google Calendar. Aeris identifies available dates, recommends a suitable flight, hotel and activities within budget, and creates a draft plan. The traveller replaces one recommendation with an option found through manual browsing.

3. Collaborative Group Travel Planner

Description: A shared trip space where members can combine schedules and preferences, discuss options, browse available travel choices, vote privately, assign a payer and approve a group itinerary. AI supports the conversation and decision process, but normal group chat and manual selection remain usable without AI.

Example: Four friends join one trip, enter their dates and budgets, discuss hotel options and share links. Aeris identifies the best overlap and privately collects votes. The organiser then confirms the selected option and completes the booking.

4. Adaptive Trip Management

Description: A planning system that helps travellers respond to delays, cancellations, closures, weather or personal changes. Users can manually search for alternatives or ask AI to analyse the remaining itinerary and prepare a revised plan. Confirmed bookings, costs and calendars are updated only after the authorised user approves the action.

Example: A cancelled flight affects the hotel arrival and evening schedule. The traveller can browse replacement flights manually or let Aeris compare alternatives and prepare a complete revised itinerary before confirming the changes.

Features

1. Travel Search Browse Filter and Comparison

Description: Users can directly browse available flights, accommodation, transport, restaurants, attractions and activities. Each category provides suitable filters, such as destination, dates, number of travellers, price range, rating, location, facilities, travel time and availability. Users can open full details, save options, compare choices and add a selected option to a draft trip. AI recommendations appear as optional assistance and do not replace the normal result list.

Example: A user searches for accommodation in Osaka, filters the results below RM250 per night and selects properties near a train station. They compare three options side by side and choose one themselves, even though Aeri recommends a different hotel.

2. Personalisation Profile and Google Calendar Connection

Description: Users answer personalisation questions about dates, budget, interests, travel pace, food requirements, accommodation style, transport preferences and accessibility needs. The answers are saved in a private travel profile and can be changed at any time. With permission, Aeri reads relevant Google Calendar availability and adds approved trip events. Calendar information is used only for the connected traveller and is not automatically exposed to other group members.

Example: A traveller selects vegetarian food, moderate travel pace and a maximum hotel price of RM180 per night. Their calendar shows an examination on 17 September, so Aeri recommends departures from 18 September onward. The traveller can still manually choose another date.

3. AI Recommendations and Itinerary Builder

Description: Aeri AI uses the traveller's profile, selected destination, available options, budget and confirmed trip details to recommend suitable combinations of flights, accommodation, transport and activities. It explains why an option fits and can generate a draft day-by-day itinerary. Users can accept, reject, replace, reorder or manually add any item. For solo travellers, this appears through a suggestion feed, smart cards and actions such as Plan My Trip, Plan My Day and Find an Alternative rather than a group-chat screen.

Example: Aeri proposes a three-day Kuala Lumpur itinerary with a morning flight, centrally located hotel, food market and cultural activities. The traveller removes one activity, searches manually for another and asks the AI to rebalance the remaining schedule.

4. Booking Checkout and Confirmation

Description: Users can prepare bookings for supported flights, accommodation, transport, restaurants and activities from either manual search results or AI recommendations. Before checkout, the application shows the provider, traveller details, dates, final price and currency, taxes or fees, important conditions and payment amount. The booking proceeds only after an authorised user presses Confirm Booking. Confirmed details are then stored in the trip and added to the itinerary and budget. Payment information must be handled by an approved payment provider rather than stored directly by Aeri.

Example: The user selects a flight from the normal search page. Aeri shows the passenger details, baggage choice, final fare and cancellation conditions. The user confirms payment, and the confirmed flight appears in the dashboard and calendar.

5. Group Creation Chat and Shared Planning

Description: An organiser creates a group trip and invites members through a link or code. Members can chat, share travel links, suggest options and view the shared itinerary. Each person has an individual account so their preferences, votes and expenses are recorded correctly. The Group AI

remembers relevant trip information from the conversation, including dates, places, links, agreed options and proposed changes, while unrelated private conversations remain outside the shared trip record.

Example: A member shares a hotel link in the group chat and another suggests a different date. Everyone can open both options, discuss them and add them to a shared decision without leaving the trip workspace.

6. AI Preference Matching Private Voting and Personal Follow Up

Description: Aeris compares each member's available dates, budget and interests, then shows the strongest shared options and any conflicts. When the group needs to decide, the system can privately ask each eligible member a Yes or No question or present several choices. Individual answers and the running count remain hidden while voting is open. The group option proceeds only when the agreed approval rule is met. If a proposal is rejected, the shared plan remains unchanged. A member who preferred the rejected option can privately request a personal alternative from Aeris.

Example: The AI identifies 20 to 22 September as the only dates that work for everyone and proposes a RM450-per-person plan. Members confirm privately. Later, only one person supports replacing a museum with a concert, so the group keeps the museum and Aeris privately offers that member a separate suggestion.

7. Central Trip Dashboard and Calendar Synchronisation

Description: The dashboard provides one confirmed view of the trip, including the day-by-day itinerary, bookings, next activity, locations, useful links, spending, group balances, pending votes, AI proposals and recent changes. Users can manually edit unconfirmed items. Approved itinerary events can be added to or updated in each connected Google Calendar. A calendar is never changed without that traveller's permission, and a proposed AI change is not synchronised until it is approved.

Example: After the group confirms Saturday's itinerary, the dashboard shows the flight, hotel and activities in order. Members who connected Google Calendar receive the approved events, while other members continue using the Aeris schedule.

8. Automatic Replanning and Alternative Search

Description: When a flight is delayed or cancelled, accommodation becomes unavailable, a venue closes, weather affects an activity or users request a change, Aeris identifies the affected itinerary items. Users may browse alternatives manually or ask AI to rank suitable replacements using available time, location, travel distance, opening information, preferences, existing bookings and remaining budget. AI can prepare a multi-item revised itinerary and assist with supported booking changes or cancellations. The system shows every schedule and cost difference before the authorised user or group approves anything.

Example: A 3:00 PM flight is cancelled. Aeris displays available replacement flights for manual comparison and recommends a 7:00 PM option. It also proposes moving hotel arrival, removing dinner and changing an evening activity. Nothing is changed or purchased until the user approves the full action.

9. Multi Currency Budget Payment and Shared Expenses

Description: Travellers set a total or per-person budget and track planned, booked and actual costs in different currencies. The system keeps the original amount and shows converted totals in the selected base currency. AI uses the remaining budget when comparing options or replanning. For group purchases, members can assign an authorised payer before checkout. Shared expenses record who paid, who participated and whether the amount is divided equally, by percentage or by custom amounts. The application updates balances and suggests simplified settlements.

Example: The group books an RM800 hotel through an assigned payer and sees RM200 per person added to the plan. Later, one member records an 8,000 Yen dinner for four people. Aeris converts and divides the expense, then updates everyone's remaining budget and balance.

10. Location Navigation and Local Discovery

Description: Users can open locations from itinerary items, view routes and explore nearby places. When connected information is available, the app can consider current location, travel time, traffic, public transport, tolls, opening information and safety notices. Users can browse nearby results manually or receive AI suggestions based on their free time, interests and budget. The system must show whether travel and availability information is current, estimated or unavailable.

Example: A solo traveller finishes lunch early and has two hours before the next calendar event. They browse nearby attractions and also ask Aeris for a suggestion. Aeris recommends a gallery that matches their interest in culture and provides a route that reaches the next activity on time.

11. Review Approval Notifications and History

Description: Before any booking, payment, cancellation or AI-generated itinerary change becomes final, Aeris shows a clear review containing the action, affected travellers, final price, budget impact, timing changes and important conditions. The authorised user can approve, reject or return to comparison. After approval, the system stores the decision, updates related trip information, synchronises permitted calendars and notifies affected members. A change history records what happened and who approved it, preventing ordinary chat messages or incorrect AI interpretations from silently changing the trip.

Example: Aeris proposes changing a flight, moving hotel arrival and cancelling dinner for an additional RM95. The group sees the old and new schedule and the relevant conditions. The assigned user approves the action, after which the dashboard, budget and connected calendars are updated.
